

## Lecture 20: Conditional expected value with respect to a sub- $\sigma$ -field

Let's start with a motivation.

Consider a box with numbered tickets which are colored.

I pick one at random & show you the color but not the number

Before you know the color your best guess for  $X$  is

$$E(X) = \int_X dP = \begin{cases} \text{average of the} \\ \text{ticket numbers} \\ \text{in the box.} \end{cases}$$

After I tell you the color is green your new best guess for  $X$  is

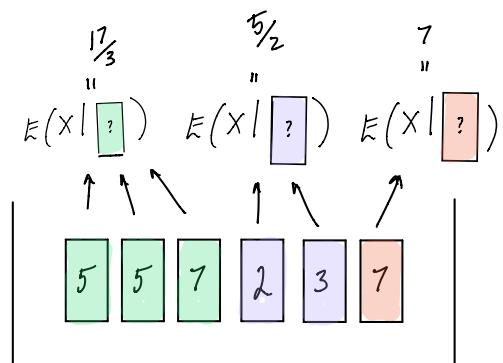

$$\begin{aligned} E(X | \text{[color]}) &= \begin{cases} \text{average green} \\ \text{ticket number} \end{cases} \\ &= \frac{5+5+7}{3} = \frac{17}{3} \end{aligned}$$

If you wanted to automate this prediction you could pre-compute

$$E(X | \text{[green]}) \quad E(X | \text{[purple]}) \quad E(X | \text{[orange]})$$

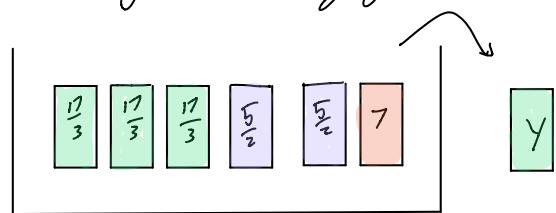

(1)

This can be thought of as a map from ticket to prediction value

(2)

or as a granular smoothing of  $X$

where  $Y = E(X | \text{color})$ .

Notice two key facts about  $Y = E(X | \text{color})$ .

- (i) The collection of events that we can place bets on for  $Y$  is less than for  $X$
- (ii) If  $A$  is an event that corresponds to a bet on  $Y$ , i.e.  $A = \{Y = \frac{22}{3}\} \cup \{Y = 7\}$ , then

$$\underbrace{\int_A X dP}_{\frac{5+5+7+7}{6}} = \underbrace{\int_A Y dP}_{\frac{17}{3} \cdot \frac{1}{2} + 7 \cdot \frac{1}{6}}$$

Now make the correspondence

(3)

$\mathcal{R}$  = the collection of tickets

$\mathcal{F}$  = the possible bets on all tickets

$\mathcal{Q}$  = the possible bets on color

For  $w \in \mathcal{R}$ ,  $X(w) = \text{ticket \#}$

$E(X|\mathcal{Q}) = Y$  maps  $w \in \mathcal{R} \mapsto$  ave  $X$  of tickets with the same color as  $w$

and we have

$E(X|\mathcal{Q})$  is  $\mathcal{Q}$ -measurable and

$$\int_A X dP = \int_A E(X|\mathcal{Q}) dP \quad \forall A \in \mathcal{Q}.$$

Theorem: (existence of  $E(X|\mathcal{Q})$ )

Let  $(\mathcal{R}, \mathcal{F}, P)$  be a probability space and  $X \in Q(\mathcal{R}, \mathcal{F}, P)$  be a possibly extended r.v.

If  $\mathcal{Q} \subset \mathcal{F}$  is a  $\sigma$ -field then  $\exists$  a  $P$ -unique extended r.v.  $E(X|\mathcal{Q}) \in Q(\mathcal{R}, \mathcal{F}, P)$  such that

- (i)  $E(X|\mathcal{Q})$  is  $\mathcal{Q}$ -measurable  $\hookrightarrow$  more granular than  $X$
- (ii)  $\int_A X dP = \int_A E(X|\mathcal{Q}) dP \quad \forall A \in \mathcal{Q}$

Proof:

Start by assuming  $X \geq 0$ .

Let  $V(\cdot) = \int \cdot dP$  be a measure on  $(\mathcal{R}, \mathcal{Q})$ .

and  $\bar{P}(\cdot) = P(\cdot)$  but only defined over  $(\mathcal{R}, \mathcal{Q})$ .

Now to show (ii) we want a  $E(X|\mathcal{Q}) @ \mathcal{Q}$

$$v(A) = \int_A E(X|\mathcal{Q}) d\bar{P}$$

↑  
replaced  $P$  with  $\bar{P}$  since  
 $E(X|\mathcal{Q})$  is supposed to be  $\mathcal{Q}$ -measurable

so look for  $dV/d\bar{P}$  this as

Notice  $V \ll \bar{P}$  since

$$\bar{P}(A) = 0, A \in \mathcal{Q} \Rightarrow \int_A X dP = 0 \quad P\text{-a.e.}$$

$$\Rightarrow v(A) = \int_A X dP = 0$$

∴ By the Radon-Nikodym Thm  $\exists$  a unique  $dV/d\bar{P} \in \eta(\mathcal{R}, \mathcal{Q})$  s.t.  $\forall A \in \mathcal{Q}$

$$\int_A \frac{dV}{d\bar{P}} d\bar{P} = V(A) = \int_A X dP$$

$$\text{So set } E(X|\mathcal{Q}) := \frac{dV}{d\bar{P}} \in \eta(\mathcal{R}, \mathcal{Q})$$

By the change of variables Thm

$$\begin{array}{ccc} \mathcal{R} & \xrightarrow{\text{id} @} & \mathcal{R} \\ \mathcal{F}, P & & \mathcal{Q}, \bar{P} \\ & \parallel & \\ & & \mathbb{R} \\ & & B(\mathbb{R}) \end{array}$$

we have

$$E(X|\mathcal{Q}) \in Q(\mathcal{R}, \mathcal{Q}, \bar{P}) \Leftrightarrow E(X|\mathcal{Q}) \circ \text{id} \in Q(\mathcal{R}, \mathcal{F}, P)$$

$$\text{and } \int_A E(X|\mathcal{Q}) dP = \int_{\text{id}^{-1}(A)} E(X|\mathcal{Q}) \circ \text{id} dP$$

$$= \int_A E(X|\mathcal{Q}) d\bar{P}$$

$$= \int_A X dP \leftarrow v(A)$$

as was to be shown.

Now just suppose  $X \in Q(\mathcal{R}, \mathcal{F}, P)$ .

Assume  $X \in Q^+(\mathcal{R}, \mathcal{F}, P)$  w.l.g.

∴  $v(\cdot) := \int \cdot dP$  is a finite measure on  $\mathcal{Q}$

$$\therefore E(X^+|\mathcal{Q}) := \frac{dV}{d\bar{P}} \in L_1(\mathcal{R}, \mathcal{Q}, \bar{P})$$

by Thm "props of RND."

∴  $E(X^+|\mathcal{Q}) \in L_1(\mathcal{R}, \mathcal{F}, P)$ , change of variables

(6)

$$\therefore E(X|\Omega) := \underbrace{E(X^+|\Omega)}_{\in L_1(\Omega, \mathcal{F}, P)} - \underbrace{E(X^-|\Omega)}_{\in \mathcal{Q}^-(\Omega, \mathcal{F})} \stackrel{P\text{-a.e. defined}}{\in} \mathcal{Q}^+(\Omega, \mathcal{F}, P)$$

and  $\forall A \in \mathcal{Q}$

$$\begin{aligned} \int_A E(X|\Omega) dP &= \int_A \underbrace{E(X^+|\Omega)}_{\in L_1} dP - \int_A \underbrace{E(X^-|\Omega)}_{\text{by Prop 3}} dP \\ &= \int_A X^+ dP - \int_A X^- dP \\ &= \int_A X dP \end{aligned}$$

This establishes (i) & (ii) &  $E(X|\Omega) \in \mathcal{Q}^+(\Omega, \mathcal{F}, P)$ .

For uniqueness suppose  $\tilde{E}(X|\Omega)$  is another version.

Now by Thm on indefinite integrals in Lecture 11

$$\begin{aligned} \int \cdot \tilde{E}(X|\Omega) dP &\stackrel{(ii)}{=} \int \cdot E(X|\Omega) dP \text{ on } \mathcal{Q} \\ \Rightarrow \tilde{E}(X|\Omega) &= E(X|\Omega) \text{ P-a.e.} \\ \Rightarrow \tilde{E}(X|\Omega) &= E(X|\Omega) \text{ P-a.e.} \quad \text{QED} \end{aligned}$$

Remark: By construction we have

$$X \in \mathcal{Q}^+(\Omega, \mathcal{F}, P) \Rightarrow E(X|\Omega) \in \mathcal{Q}^+(\Omega, \mathcal{F}, P)$$

$$X \in \mathcal{Q}^-(\Omega, \mathcal{F}, P) \Rightarrow E(X|\Omega) \in \mathcal{Q}^-(\Omega, \mathcal{F}, P).$$

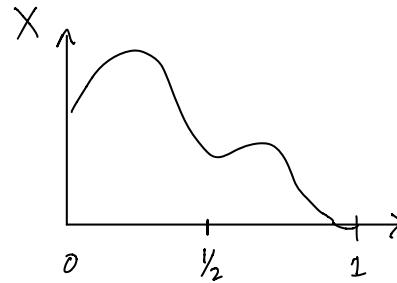

Remark: One way to think about  $E(X|\Omega)$  is

$$E(X|\Omega)(w) = E(X \mid \text{the sets } A \in \mathcal{Q} \text{ s.t. } w \in A)$$

A slightly more rigorous view is to think of  $E(X|\Omega)(w)$  as the weighted average of  $X$  over the "smallest  $\mathcal{Q}$ -set" containing  $w$ , i.e. a smoothing or granulation of  $X$ , or a projection of  $X$  onto the space of  $\mathcal{Q}$ -measurable functions.

Example:

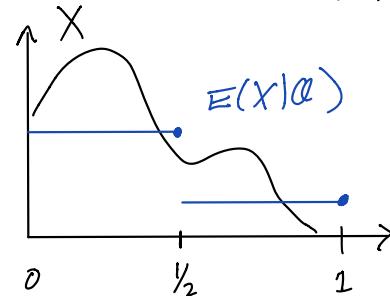

$$(\Omega, \mathcal{F}, P) = ([0,1], \mathcal{B}([0,1]), P)$$

$$\mathcal{Q} = \{\emptyset, \Omega, [0, \frac{1}{2}], [\frac{1}{2}, 1]\}$$

Guess at  $E(X|\Omega)$  & show it has the correct properties

$$E(X|\Omega)(w) := \begin{cases} \frac{E(I_{[0, \frac{1}{2}]} X)}{P([0, \frac{1}{2}])} & \text{if } w \in [0, \frac{1}{2}] \\ \frac{E(I_{[\frac{1}{2}, 1]} X)}{P([\frac{1}{2}, 1])} & \text{if } w \in (\frac{1}{2}, 1] \end{cases}$$

$E(X|\Omega)$  is  $\mathcal{Q}$ -measurable (it's a simple function w.r.t.  $\mathcal{Q}$ )

$$E(X|\Omega) \in \mathcal{Q}(\Omega, \mathcal{F}, P)$$

Also if  $A = [0, \frac{1}{2}]$

$$\begin{aligned} \int_A E(X|\Omega) dP &= \int_A \frac{E(I_{[0, \frac{1}{2}]} X)}{P([0, \frac{1}{2}])} dP \\ &= \int_A X dP \end{aligned}$$

and similarly for  $A = \emptyset, \Omega$  or  $(\frac{1}{2}, 1]$ .

$\therefore E(X|\Omega)$  has the desired properties and is the P-a.e. unique such choice.

Example

Let  $(\Omega, \mathcal{F}, P)$  be a probability space and  $X \in \mathcal{Q}(\Omega, \mathcal{F}, P)$ . Suppose

$$\{\emptyset, \Omega\} = \mathcal{F}_0 \subset \mathcal{F}_1 \subset \dots \subset \mathcal{F}$$

is an increasing sequence of sub- $\sigma$ -fields

Then

$$E(X|\mathcal{F}_0), E(X|\mathcal{F}_1), \dots, E(X|\mathcal{F})$$

$$\begin{array}{ccc} \overset{\parallel}{E(X)} & \xrightarrow{\text{increasing resolution approx}} & \overset{\parallel}{X} \\ & \text{to } X & \end{array}$$

Example:

This example shows how to understand  $E(X|\mathcal{Q})$  as a projection when  $X \in L_2(\Omega, \mathcal{F}, P)$ .

Define

$$S := \{Y \in L_2(\Omega, \mathcal{F}, P) : Y \text{ is } \mathcal{Q}\text{-measurable}\}$$

Notice that  $S$  a closed linear subspace of  $L_2(\Omega, \mathcal{F}, P)$  by the Closure thm.

The projection  $P_S X$  satisfies

$$X - P_S X \perp w \quad \forall w \in S$$

$$\therefore E((X - P_S X)w) = 0 \quad \forall w \in S$$

$$\therefore E(Xw) = E(P_S Xw) \quad \forall w \in S$$

Given  $A \in \mathcal{Q}$ , set  $w = \mathbf{1}_A \in S$  so that

$$\int_A X dP = \int_A P_S X dP$$

Since  $P_S X \in S \subset L_2(\Omega, \mathcal{F}, P)$  we have

$$E(X|\mathcal{Q}) = P_S X. \quad P\text{-a.e.}$$

(7)

Example

$$\Omega = [-1, 1]$$

$$\mathcal{F} = \mathcal{B}([-1, 1])$$

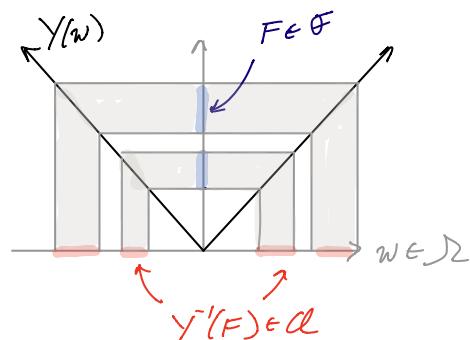

$$dP = \delta(w) dw$$

Let  $X \in \mathcal{Q}(\Omega, \mathcal{F}, P)$  and define

$$Y(w) = |w| \quad \text{on } w \in \Omega \quad \text{so that}$$

$$\sigma(Y) = Y^{-1}(\mathcal{F}) \subset \mathcal{F}$$

pull back  
of a single  
map

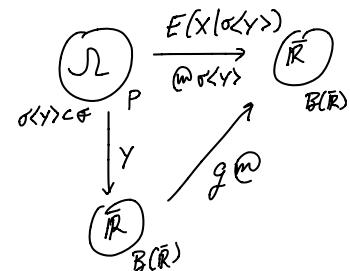

To make a guess at what  $E(X|\sigma(Y))$  is notice

$$E(X|\sigma(Y)) \cap \sigma(Y)$$

↓ Lecture 8

$$E(X|\sigma(Y))(w) = g(Y(w))$$

$$= g(|w|)$$

so  $E(X|\sigma(Y))(w) = g(|w|)$  for some measurable  $g$ . Since the "smallest  $\sigma(Y)$  sets containing  $w$  are of the form  $\{w, -w\}$ " set

$$E(X|\sigma(Y))(w) = X(w) \frac{\delta(w)}{\delta(w) + \delta(-w)} + X(-w) \frac{\delta(-w)}{\delta(w) + \delta(-w)}$$

= weighted ave of  $X$  over  $\{w, -w\}$  with weights given by the density of  $P$  w.r.t. Lebesgue measure.

(9) Since this  $E(X|\sigma(Y))$  is a  $\mathcal{Q}$  function of  $w$  it is  $\sigma(Y)$ -measurable.

Since  $E(X|\sigma(Y)) \geq 0$  it is in  $L^1(\Omega, \mathcal{F}, P)$ .

To show that it is the conditional expected value of  $X$  w.r.t.  $\sigma(Y)$  just check it integrates the same as  $X$  over sets  $A \in \sigma(Y)$ .

Indeed if  $A \in \sigma(Y)$  then  $A = -A$  so

$$\begin{aligned} & \int_A E(X|\sigma(Y)) dP \\ &= \int_A X(w) \frac{f(w)}{f(w) + f(-w)} f(w) dw \\ &+ \underbrace{\int_A X(-w) \frac{f(-w)}{f(w) + f(-w)} f(w) dw}_{\text{By change of variables}} \\ &\quad \text{this is } \int_{-A} X(w) \frac{f(w)}{f(w) + f(-w)} f(-w) dw \\ &= \int_A X(w) \frac{f(w)}{f(w) + f(-w)} [f(w) + f(-w)] dw \\ &= \int_A X dP \end{aligned}$$

## Properties of $E(X|\mathcal{Q})$

(10)

These come in two flavors:

- 1) Properties of  $E(X|\mathcal{Q})$  that resemble properties of integration & expected value
- 2) Properties of  $E(X|\mathcal{Q})$  which mimic that of a smoothing operator.

Assumptions: To state the results more clearly assume throughout this section that  $X, Y, X_1, X_2, \dots$  are quasi-integrable extended r.v.s on a prob space  $(\Omega, \mathcal{F}, P)$  &  $\mathcal{Q}, \mathcal{Q}_1, \mathcal{Q}_2, \dots$  are sub- $\sigma$ -fields of  $\mathcal{F}$ .

## Theorem: (Smoothing properties of $E(X|\mathcal{Q})$ )

- (s1)  $E(E(X|\mathcal{Q})) = E(X)$
- (s2) If  $\mathcal{Q}_1 \subset \mathcal{Q}_2$  (i.e.  $\mathcal{Q}_1$  smooths more) Then  $E(E(X|\mathcal{Q}_2)|\mathcal{Q}_1) \stackrel{P-a.e.}{=} E(X|\mathcal{Q}_1)$

- (s3)  $X \in L^1(\Omega, \mathcal{F}, P) \iff E(X|\mathcal{Q}) \in L^1(\Omega, \mathcal{F}, P)$
- (s4) If  $X$  is  $\mathcal{Q}$ -measurable then  $E(XY|\mathcal{Q}) \stackrel{P-a.e.}{=} X E(Y|\mathcal{Q})$

and in particular  
 $E(X|\mathcal{Q}) \stackrel{P-a.e.}{=} X$

(Note: (s4) implicitly assumes  $XY$  is  
 Quasi-integrable ... along with  $X$  &  $Y$ )

(11)

we will also give the result for the expected value properties of  $E(X|\Omega)$  &

then prove both together (since proving (s4), for example, uses the following linearity results).

Theorem: (expected value properties of  $E(X|\Omega)$ )

$$(e_1) \quad E(cX|\Omega) \stackrel{P.a.e.}{=} cE(X|\Omega) \quad c \in \mathbb{R}.$$

$$(e_2) \quad E(X+Y|\Omega) = E(X|\Omega) + E(Y|\Omega)$$

P-a.e. on the set where

$E(X|\Omega) + E(Y|\Omega)$  is defined (i.e. not  $\pm\infty$ ).

Note: There is an implicit assumption here that  $X, Y, X+Y \in \mathcal{Q}(\mathcal{A}, \mathcal{F}, P)$  but not necessarily of the same class.

$$(e_3) \quad X \stackrel{P.a.e.}{\leq} Y \Rightarrow E(X|\Omega) \stackrel{P.a.e.}{\leq} E(Y|\Omega)$$

$$(e_4) \quad |E(X|\Omega)| \leq E(|X||\Omega)$$

(e<sub>5</sub>) If  $0 \leq X_n \uparrow X$  P-a.e. then

$$\stackrel{\uparrow}{\text{MCf}} \quad 0 \leq E(X_n|\Omega) \uparrow E(X|\Omega) \quad \text{P-a.e.}$$

$$(e_6) \quad \text{If } 0 \leq X_n \text{ P.a.e. } n \in \mathbb{N} \text{ then}$$

$\stackrel{\uparrow}{\text{Fatou}} \quad E(\liminf_n X_n |\Omega) \leq \liminf_n E(X_n|\Omega)$

$$(e_7) \quad \text{If } X_n \xrightarrow{a.e.} X \text{ then}$$

$\stackrel{\uparrow}{\text{Def}} \quad E(X_n|\Omega) \xrightarrow{a.e.} E(X|\Omega)$

on the set  $\{E(\sup_n |X_n| |\Omega) < \infty\}$

(12)

Before we prove the above two Theorems we need the following lemma.

Lemma: If  $X \in \mathcal{Q}(\mathcal{A}, \mathcal{F}, P)$  then  $\forall A \in \mathcal{Q}$

$$E(I_A X |\Omega) \stackrel{P.a.e.}{=} I_A E(X|\Omega)$$

Proof:

Clearly  $I_A E(X|\Omega)$  is  $\mathcal{Q}$ -a.e. & in  $\mathcal{Q}(\mathcal{A}, \mathcal{F}, P)$ .

Also  $\forall \tilde{A} \in \mathcal{Q}$

$$\int \limits_{\tilde{A}} I_A E(X|\Omega) dP = \int \limits_{A \cap \tilde{A}} E(X|\Omega) dP$$

$$\stackrel{\text{def}}{=} \int \limits_{A \cap \tilde{A}} X dP \quad \text{since } A \cap \tilde{A} \in \mathcal{Q}$$

$$= \int \limits_{\tilde{A}} I_A X dP$$

$$\stackrel{\text{def}}{=} \int \limits_{\tilde{A}} E(I_A X |\Omega) dP$$

$$\therefore E(I_A X |\Omega) \stackrel{P.a.e.}{=} I_A E(X|\Omega) \quad \text{by uniqueness}$$

Q.E.D

Proof of (s1)-(s4) & (e1)-(e7):

(s1) follows simply by the requirement:

$$\int \limits_A X dP = \int \limits_A E(X|\Omega) dP \quad \text{when } A = \mathcal{A} \in \mathcal{Q}.$$

(s2) we show  $E(X|\Omega_1)$  is a version of  $E(E(X|\Omega_1)|\Omega_2)$  and  $E(E(X|\Omega_2)|\Omega_1)$ .

Note  $E(X|\Omega_1)$  is both  $\Omega_1$  &  $\Omega_2$  measurable and in  $\mathcal{Q}(\mathcal{A}, \mathcal{F}, P)$ .

Now if  $A \in \mathcal{Q}_1$ ,  $E(E(X|\mathcal{Q}_2)|\mathcal{Q}_1)$  satisfies (13)

$$\int_A E(E(X|\mathcal{Q}_2)|\mathcal{Q}_1) dP \stackrel{\text{def}}{=} \int_A E(X|\mathcal{Q}_2) dP$$

... but so does  $E(X|\mathcal{Q}_1)$  since

$$\begin{aligned} \int_A E(X|\mathcal{Q}_1) dP &\stackrel{\text{def}}{=} \int_A X dP \\ &\stackrel{\text{def}}{=} \int_A E(X|\mathcal{Q}_2) dP \quad \text{since } A \in \mathcal{Q}_1 \subset \mathcal{Q}_2 \end{aligned}$$

$$\therefore E(X|\mathcal{Q}_1) \stackrel{\text{P-a.e.}}{=} E(E(X|\mathcal{Q}_2)|\mathcal{Q}_1).$$

$$\text{& similarly } E(X|\mathcal{Q}_1) \stackrel{\text{P-a.e.}}{=} E(E(X|\mathcal{Q}_1)|\mathcal{Q}_2).$$

(53) This is just what the remark was following  
The Theorem establishing the existence of  
 $E(X|\mathcal{Q})$ .

(e1) This clearly follows from Big 3.

(e2): We show if  $X, Y, X+Y \in \mathcal{Q}(\mathcal{I}, \mathcal{F}, P)$   
then  $\mathbb{E}_A [E(X+Y|\mathcal{Q})] \stackrel{\text{P-a.e.}}{=} \mathbb{E}_A E(X|\mathcal{Q}) + \mathbb{E}_A E(Y|\mathcal{Q})$   
where  $A := \{E(X|\mathcal{Q}) + E(Y|\mathcal{Q}) \text{ is defined}\}$ . ↑  
↑ equals  
if the sum is defined.

case 1:  $X \& Y$  are in  $\mathcal{Q}^-(\mathcal{I}, \mathcal{F}, P)$ .

Now by (53)  $E(X|\mathcal{Q}) \in \mathcal{Q}^-$  &  $E(Y|\mathcal{Q}) \in \mathcal{Q}^-$   
so we may change them on  $P$ -null sets so  
that  $E(X|\mathcal{Q}) > -\infty$  &  $E(Y|\mathcal{Q}) > -\infty$   
everywhere on  $\mathcal{I}$ .

Now  $E(X|\mathcal{Q}) + E(Y|\mathcal{Q}) > -\infty$  & is  
therefore in  $\mathcal{Q}^-$  & is  $\mathcal{Q}$ -measurable  
by the closure theorem.

we also have  $\mathbb{E}_A E(X|\mathcal{Q})$  (14)

$$\int_A E(X|\mathcal{Q}) + E(Y|\mathcal{Q}) dP$$

$$\stackrel{\text{Big 3}}{=} \int_A E(X|\mathcal{Q}) dP + \int_A E(Y|\mathcal{Q}) dP$$

$$\stackrel{\text{def}}{=} \int_A X dP + \int_A Y dP$$

$$\stackrel{\text{Big 3}}{=} \int_A X+Y dP$$

$$\therefore E(X+Y|\mathcal{Q}) = E(X|\mathcal{Q}) + E(Y|\mathcal{Q}) \text{ P-a.e. on } \mathcal{I}.$$

case 2:  $X, Y, X+Y \in \mathcal{Q}(\mathcal{I}, \mathcal{F}, P)$ .

For  $-\infty < c \leq 0$  define

$$A_c := \{E(X|\mathcal{Q}) \geq c\} \cap \{E(Y|\mathcal{Q}) \geq c\} \in \mathcal{Q}$$

Now the previous lemma shows

$$E(\mathbb{E}_{A_c} X|\mathcal{Q}) \stackrel{\text{P-a.e.}}{=} \mathbb{E}_{A_c} E(X|\mathcal{Q}) \geq c > -\infty$$

$$E(\mathbb{E}_{A_c} Y|\mathcal{Q}) \stackrel{\text{P-a.e.}}{=} \mathbb{E}_{A_c} E(Y|\mathcal{Q}) \geq c > -\infty$$

The previous case now applies & gives

$$E(\mathbb{E}_{A_c} X + \mathbb{E}_{A_c} Y|\mathcal{Q}) \stackrel{\text{P-a.e.}}{=} \mathbb{E}(\mathbb{E}_{A_c} X|\mathcal{Q}) + \mathbb{E}(\mathbb{E}_{A_c} Y|\mathcal{Q})$$

ii Lemma

$$\mathbb{E}_{A_c} E(X+Y|\mathcal{Q}) = \mathbb{E}_{A_c} E(X|\mathcal{Q}) + \mathbb{E}_{A_c} E(Y|\mathcal{Q})$$

$$\therefore E(X+Y|\mathcal{Q}) = E(X|\mathcal{Q}) + E(Y|\mathcal{Q}) \text{ P-a.e. on }$$

$$A_{-\infty} := \bigcup_{c \in \mathcal{Q}^-} A_c = \{E(X|\mathcal{Q}) > -\infty \text{ and } E(Y|\mathcal{Q}) > -\infty\}$$

A similar argument shows

$$E(X+Y|\mathcal{Q}) = E(X|\mathcal{Q}) + E(Y|\mathcal{Q}) \text{ P-a.e. on }$$

$$A_{\infty} := \{E(X|\mathcal{Q}) < \infty \text{ and } E(Y|\mathcal{Q}) < \infty\}$$

To finish simply notice  $A_\alpha \cup A_{-\alpha}$  is (15)  
exactly the set  $\{E(X|\Omega) + E(Y|\Omega) \text{ is defined}\}.$

(e3): show  $X \stackrel{\text{P.a.e.}}{\leq} Y \Rightarrow E(X|\Omega) \stackrel{\text{P.a.e.}}{\leq} E(Y|\Omega).$

This follows from the indefinite integral results in Lecture 11. Indeed

$$\begin{aligned} \int_A X dP &\leq \int_A Y dP \quad \forall A \in \mathcal{Q} \\ \Rightarrow \int_A E(X|\Omega) dP &\leq \int_A E(Y|\Omega) dP, \quad \forall A \in \mathcal{Q} \\ \xrightarrow{\text{lecture 11}} \quad E(X|\Omega) &\stackrel{\text{P.a.e.}}{\leq} E(Y|\Omega) \end{aligned}$$

(e4): show  $|E(X|\Omega)| \leq E(|X| |\Omega)$

This follows from (e3) since it implies

$$-E(|X| |\Omega) \leq E(X|\Omega) \leq E(|X| |\Omega) \quad \text{P.a.e.}$$

(e5): show if  $0 \leq X_n \uparrow X$  P-a.e. then MCT  $0 \leq E(X_n|\Omega) \uparrow E(X|\Omega)$  P-a.e.

Note that (e3) establishes that

$$0 \leq E(X_n|\Omega) \uparrow \quad \text{P.a.e.}$$

$\therefore \lim_n E(X_n|\Omega)$  exists and is in  $\mathbb{Q}^-(\Omega, \mathcal{A}, P)$

by non-negativity & closure.

Similarly  $X \in \mathbb{Q}^-(\Omega, \mathcal{A}, P).$

We show  $\lim_n E(X_n|\Omega) \stackrel{\text{P.a.e.}}{=} E(X|\Omega).$

Indeed  $\forall A \in \mathcal{Q}$

$$\begin{aligned} \int_A \lim_n E(X_n|\Omega) dP &\stackrel{\text{MCT}}{=} \lim_n \int_A E(X_n|\Omega) dP \\ &\stackrel{\text{def}}{=} \lim_n \int_A X_n dP \\ &\stackrel{\text{MCT}}{=} \int_A \lim_n X_n dP \\ &\quad \xrightarrow{X} \end{aligned}$$

$\therefore$  by the characterizing properties of  $E(X|\Omega)$  we have

$$\lim_n E(X_n|\Omega) \stackrel{\text{P.a.e.}}{=} E(X|\Omega)$$

(e6) Fatou. This is similar to (e5).

(e7) show that if  $X_n \xrightarrow{\text{a.e.}} X$  &  $X, X_n \in \mathbb{Q}(\Omega, \mathcal{A}, P)$  then

$$\int_A E(X_n|\Omega) \xrightarrow{\text{a.e.}} \int_A E(X|\Omega)$$

where  $A := \{E(\sup_n |X_n| |\Omega) < \infty\}.$

Let  $0 \leq c < \infty$  & set

$$A_c := \left\{ E\left(\sup_n |X_n|\right) |\Omega) \leq c \right\} \in \mathcal{Q}$$

$$\therefore \underbrace{E\left(\sup_n |I_{A_c} X_n|\right)}_{\text{Lemma}} |\Omega)$$

$$\begin{aligned} &\stackrel{\text{P.a.e.}}{=} \int_{A_c} E\left(\sup_n |X_n|\right) |\Omega) \\ &\leq c \end{aligned}$$

$$\therefore E\left(\sup_n |I_{A_c} X_n|\right) \in L_1(\Omega, \mathcal{A}, P)$$

$$\therefore \sup_n |I_{A_c} X_n| \in L_1(\Omega, \mathcal{A}, P) \text{ by (e3)}$$

Now setting  $Y = \sup_n |I_{A_n} X_n|$  (17)

$$E\left(\liminf_n \underbrace{(Y + I_{A_n} X_n)}_{\geq 0} \mid \Omega\right) \stackrel{P-a.e.}{\leq} \liminf_n E(Y + I_{A_n} X_n \mid \Omega)$$

by Fatou. Then by canceling  $E(Y \mid \Omega)$  from both sides (possible since  $Y \in L_1 \Rightarrow E(Y \mid \Omega) < \infty$  P-a.e.) we get

$$E\left(\liminf_n I_{A_n} X_n \mid \Omega\right) \stackrel{P-a.e.}{\leq} \liminf_n E(I_{A_n} X_n \mid \Omega)$$

Therefore

$$I_{A_c} E\left(\liminf_n X_n \mid \Omega\right) \stackrel{P-a.e.}{\leq} I_{A_c} \liminf_n E(X_n \mid \Omega)$$

Similarly

$$I_{A_c} \limsup_n E(X_n \mid \Omega) \stackrel{P-a.e.}{\leq} I_{A_c} E\left(\limsup_n X_n \mid \Omega\right)$$

so that

$$I_{A_c} \lim_n E(X_n \mid \Omega) \stackrel{P-a.e.}{=} I_{A_c} E(X \mid \Omega)$$

$$\therefore I_A \lim_n E(X_n \mid \Omega) \stackrel{P-a.e.}{=} I_A E(X \mid \Omega)$$

$$\text{for } A := \bigcup_{c \in \mathbb{Q}^+} A_c = \left\{ E\left(\sup_n |X_n| \mid \Omega\right) < c \right\} \in \mathcal{Q}.$$

(18)

(54) Show that if  $X, Y, XY \in \mathcal{Q}(\Omega, \mathcal{F}, P)$  and  $X @ \Omega$  then  $E(XY \mid \Omega) \stackrel{P-a.e.}{=} X E(Y \mid \Omega)$ .

case 1:  $X, Y \in \mathcal{Q}(\Omega, \mathcal{F}, P)$  &  $X @ \Omega$

By the lemma  $\int_A Y dP$

$$\int_A I_A E(Y \mid \Omega) dP = \int_A I_A Y dP.$$

By the structure thm  $\exists$  non-negative simple functions ( $@ \Omega$ )  $X_n$  s.t.

$$0 \leq X_n \uparrow X.$$

By linearity (e2) & MCT (e5) we have

$$\int_A X_n E(Y \mid \Omega) dP \stackrel{e2}{=} \int_A X_n Y dP.$$

$$\stackrel{e5}{\downarrow} n \rightarrow \infty \quad \stackrel{e5}{\downarrow} n \rightarrow \infty$$

$$\int_A X E(Y \mid \Omega) dP = \int_A X Y dP$$

Since  $X E(Y \mid \Omega)$  is  $@ \Omega$  by closure & in  $\mathcal{Q}(\Omega, \mathcal{F})$

we have  $X E(Y \mid \Omega) \stackrel{P-a.e.}{=} E(XY \mid \Omega)$

Case 2:  $X, Y, XY \in \mathcal{Q}(\Omega, \mathcal{F}, P)$  &  $X @ \Omega$

$$XY = (X^+ - X^-)(Y^+ - Y^-)$$

$$\begin{aligned} &= (X^+ Y^+ + Y^- Y^-) - (X^- Y^+ + X^+ Y^-) \\ &= (XY)^+ - (XY)^- \end{aligned}$$

$$\therefore E(XY|\alpha) \stackrel{def}{=} E((XY)^+|\alpha) - E((XY)^-|\alpha) \quad (19)$$

$$\stackrel{P-a.e.}{=} E(X^+Y^+|\alpha) + E(X^-Y^-|\alpha)$$

$$-E(X^-Y^+|\alpha) - E(X^+Y^-|\alpha)$$

$$\stackrel{P-a.e.}{=} X^+ E(Y^+|\alpha) + X^- E(Y^-|\alpha)$$

$$-X^- E(Y^+|\alpha) - X^+ E(Y^-|\alpha)$$

$$= (X^+ - X^-)(E(Y^+|\alpha) - E(Y^-|\alpha))$$

$$\stackrel{P-a.e.}{=} X E(Y|\alpha).$$

QED

Remark: Notice the technique for showing

the linearity (e2) & the DCT (e7) ...

regularize with  $\mathbb{I}_{A_c}$ , use the lemma

to show  $\mathbb{I}_{A_c} E(X|\alpha) \stackrel{a.e.}{=} \mathbb{I}_{A_c} E(Y|\alpha)$  then

take a countable union over  $A_c$  sets.

Let's do a quick example that shows the generality of (e2). (20)

Example:

$$(\Omega, \mathcal{F}, P) = ([0,1], \mathcal{B}([0,1]), \text{Lebesgue measure})$$

$$\mathcal{A} = \{\emptyset, \Omega, [0, \frac{1}{2}], [\frac{1}{2}, 1]\}$$

$$X(w) = \frac{1}{w}$$

Now P-a.e. we have

$$E(X|\alpha) = \begin{cases} \infty & \text{on } [0, \frac{1}{2}] \\ 2\log 2 & \text{on } [\frac{1}{2}, 1] \end{cases} \quad \& \quad E(-X|\alpha) = -E(X|\alpha)$$

and

$$\mathbb{I}_{[\frac{1}{2}, 1]} E(X-X|\alpha) \stackrel{a.e.}{=} \mathbb{I}_{[\frac{1}{2}, 1]} E(X|\alpha) + \mathbb{I}_{[\frac{1}{2}, 1]} E(-X|\alpha)$$

but you can't remove the indicator since the RHS is not defined.
